

Lesson 4

# **DAX Essentials: Foundations of Data Analysis Expressions**

Unlock the Power of Calculated Measures & Columns

March 2025

# Power BI Desktop **workflow.**

From Data to Insights

## Workflow

**Connect → Transform → Model → Visualize → Publish**

*Power BI Desktop streamlines the process from raw data to actionable insights, enabling better decision-making.*

# Power BI Desktop **workflow.**

From Data to Insights

Before cleaning data ...

The fundamentals of DAX, **essential functions, and practical applications in Power BI** to enhance data modeling, create custom calculations, and optimize analytics performance.

# What is DAX and Why?

## Definition

- DAX (Data Analysis Expressions) is a formula language used in Power BI, Power Pivot, and Analysis Services for data modeling and analysis.
- It enables the creation of calculated columns, measures, and custom tables for dynamic reporting.

## Purpose of DAX:

- Perform custom calculations on your data.
- Enable dynamic aggregations that respond to slicers, filters, and visuals.
- Implement time intelligence for analyzing trends over time.
- Build powerful data models with advanced relationships and dependencies.

# Key Features of DAX:

## Calculated Columns:

Increases model size

- Created at the row level (Stored in a table, recalculates for each row).
- Good for precomputed values (e.g., “Profit = Sales - Cost”).
- Increases model size (Stored in the dataset).

## Measures:

Dynamic calculation

- Created at the column level but calculated only when used in visuals.
- More efficient (reduces model size & improves performance).
- Good for dynamic calculations

# Calculated columns.

Enhancing your Power BI tables with row-level calculations.

## Definition

- A calculated column is a new column created using DAX formulas that computes values row by row based on existing columns in the table.
- Where are they used: Adding new fields that depend on other columns (e.g., profit, full name, categories).

1 Order type = IF('Sales Data'[OrderQuantity]>1, "Single", "Multi")

| OrderDate                    | StockDate                    | OrderNuml | ProductKey | CustomerKey | TerritoryKey | Orde | Orde | Price   | Cost       | Order type | Revenue segment |

# Calculated columns.

Enhancing your Power BI tables with row-level calculations.

## How Calculated Columns Work

### Row Context:

- Each row in the table is evaluated individually when calculating the column.

### Stored in the Data Model:

- Unlike measures, calculated column values are precomputed and stored.
- This can increase the file size, especially with large datasets.

1 Order type = IF('Sales Data'[OrderQuantity]>1, "Single", "Multi")

| OrderDate                    | StockDate                    | OrderNuml | ProductKey | CustomerKey | TerritoryKey | Orde | Orde | Price   | Cost       | Order type | Revenue segment |

# When to Use Calculated Columns?

Enhancing your Power BI tables with row-level calculations.

## Static Row-Level Calculations & Classification

- Profit for each transaction (Revenue - Cost).
- Full names by combining first and last names.

1 order type = IF(fact\_order[quantity] > 1, "Multiple", "Single")

| customer id | payment id | purchase date                | shipping id | loyalty | rating | quantity | cost        | product id     | status    | Start of Month | order type |

# DAX Measures.

*Dynamic calculations for powerful analytics.*

## Definition

- A measure in DAX is a formula used to perform calculations on aggregated data, dynamically adjusting based on the filter context in reports and visuals.

```
M_Total revenue = SUMX ('Sales Data', 'Sales Data'[OrderQuantity]* RELATED('Product'[ProductPrice]))
```

```
M_Total unit sold = SUM('Sales Data'[OrderQuantity])
```

```
M_Profit margin = [M_Profit]/[M_Revenue]
```

# Purpose of DAX measures.

*Dynamic calculations for powerful analytics.*

## Dynamic Calculations:

- Measures automatically update in response to applied filters and visualizations.

## Efficiency:

- Measures do not contribute to the size of the data model because they are not saved.

## Reusability:

- A single measure can be utilized in various visuals and reports.

## Advanced Analytics:

- Allow for intricate calculations such as time intelligence and conditional aggregations.

# Implicit vs. Explicit Measures.

Understanding the difference for better analytics.

## Definition

- An **implicit measure** is automatically created by Power BI when you drag a numeric field into a visual's Values area.
- An explicit measure is manually created by the user using a DAX formula, offering full control over the calculation.

| Aspect        | Implicit Measures                               | Explicit Measures                         |
|---------------|-------------------------------------------------|-------------------------------------------|
| Creation      | Automatic (dragging a field into a visual).     | Manual (using DAX formulas).              |
| Customization | Limited to predefined aggregations (e.g., SUM). | Fully customizable using DAX.             |
| Reusability   | Cannot be reused outside the visual.            | Can be reused across visuals and reports. |
| Complexity    | Simple aggregations only.                       | Supports complex calculations.            |
| Visibility    | Exists only in the visual.                      | Visible in the Fields pane.               |
| Performance   | Suitable for simple needs.                      | Optimized for advanced scenarios.         |

# Implicit vs. Explicit Measures.

*Understanding the difference for better analytics.*

## Implicit measures

→ is automatically created by Power BI when you drag a numeric field into a visual's Values area.

# Implicit vs. Explicit Measures.

*Understanding the difference for better analytics.*

## explicit measure

→ is manually created by the user using a DAX formula, offering full control over the calculation.

# Comparison: Calculated Columns vs. Measures.

*Understanding the difference for better analytics.*

| Aspect              | Calculated Columns                              | Measures                                                      |
|---------------------|-------------------------------------------------|---------------------------------------------------------------|
| Purpose             | Create new fields for row-level calculations.   | Perform aggregations or calculations dynamically.             |
| Calculation Context | Works on <b>row context</b> (row by row).       | Works on <b>filter context</b> (affected by slicers/filters). |
| Storage             | Values are stored in the data model.            | Values are not stored; they are computed when needed.         |
| Reusability         | Used as fields in visuals or for relationships. | Reusable across visuals and reports.                          |
| Performance Impact  | Increases data model size.                      | More efficient as they don't store results.                   |
| Flexibility         | Limited to row-level calculations.              | Suitable for dynamic aggregations and complex scenarios.      |
| Creation Context    | Calculated for each row in a table.             | Calculated dynamically based on the visual's filters.         |
| Example Use Case    | Calculating profit per transaction (row-level). | Calculating total sales or profit margin.                     |

# The structure of a DAX formula.

*A Beginner's Guide to Writing DAX Formulas.*

MEASURE NAME with "="

Total Sale = SUM ( Sales[Revenue] )

Referenced  
TABLE NAME

Referenced  
COLUMN NAME

FUNCTION NAME

Calculated columns don't always use functions, but measures do:

- In a **Calculated Column**, = Sales[Revenue] returns the value from the quantity column in each row (since it evaluates one row at a time)
- In a **Measure**, = Sales[Revenue] will return an error since Power BI doesn't know how to translate that as a single value

## REFERENCES

- Points to tables or columns in the data model.
- Format: **TableName[ColumnName]**.

# Overview of DAX function categories.

A Beginner's Guide to Writing DAX Formulas.

## MATH & STATS Functions

Functions used for **aggregation** or iterative, row-level calculations

### Common Examples:

- SUM
- AVERAGE
- MAX/MIN
- DIVIDE
- COUNT/COUNTA
- COUNTROWS
- DISTINCTCOUNT

### Iterator Functions:

- SUMX
- AVERAGEX
- MAXX/MINX
- RANKX
- COUNTX

## LOGICAL Functions

Functions that use **conditional expressions** (IF/THEN statements)

### Common Examples:

- IF
- IFERROR
- AND
- OR
- NOT
- SWITCH
- TRUE
- FALSE

## TEXT Functions

Functions used to manipulate **text strings** or **value formats**

### Common Examples:

- CONCATENATE
- COMBINEVALUES
- FORMAT
- LEFT/MID/RIGHT
- UPPER/LOWER
- LEN
- SEARCH/FIND
- REPLACE
- SUBSTITUTE
- TRIM

## FILTER Functions

Functions used to **manipulate table** and **filter contexts**

### Common Examples:

- CALCULATE
- FILTER
- ALL
- ALLEXCEPT
- ALLSELECTED
- KEEPFILTERS
- REMOVEFILTERS
- SELECTEDVALUE

## TABLE Functions

Functions that **create** or **manipulate tables** and output tables vs. scalar values

### Common Examples:

- SUMMARIZE
- ADDCOLUMNS
- GENERATESERIES
- DISTINCT
- VALUES
- UNION
- INTERSECT
- TOPN

## DATE & TIME Functions

Functions used to manipulate **date & time values** or handle time intelligence calculations

### Common Examples:

- DATE
- DATEDIFF
- YEARFRAC
- YEAR/MONTH
- DAY/HOUR
- TODAY/NOW
- WEEKDAY
- WEEKNUM
- NETWORKDAYS

### Time Intelligence:

- DATESYTD
- DATESMTD
- DATEADD
- DATESBETWEEN

## RELATIONSHIP Functions

Functions used to **manage & modify table relationships**

### Common Examples:

- RELATED
- RELATEDTABLE
- CROSSFILTER
- USERELATIONSHIP

Note: This is NOT a comprehensive list. DAX contains more than 250 different functions!

# **Math Stats Functions.**

*A Beginner's Guide to Writing DAX Formulas.*

# Aggregation functions.

Perform calculations across a column or table, returning a single aggregated value.

## Key functions

**SUM**: Adds up all values in a column.

Example: *TotalRevenue* = **SUM**(Sales[Revenue])

**AVERAGE**: Calculates the mean of a column.

Example: *AvgSales* = **AVERAGE**(Sales[Revenue])

**MAX**: Finds the highest value in a column.

Example: *MaxSales* = **MAX**(Sales[Revenue])

**MIN**: Finds the lowest value in a column.

Example: *MinSales* = **MIN**(Sales[Revenue])

# DAX Iterators (Aggregation functions X)

Perform calculations across a column or table, returning a single aggregated value.

## Key functions

| Iterator Function | Description                                             | Example Use Case                                                                   |
|-------------------|---------------------------------------------------------|------------------------------------------------------------------------------------|
| SUMX              | Adds up calculated row values                           | <code>SUMX(Sales, Sales[Price] * Sales[Quantity])</code> (Total Revenue)           |
| AVERAGEX          | Finds the average of row-wise calculations              | <code>AVERAGEX(Sales, Sales[Price] * Sales[Quantity])</code> (Avg. Order Value)    |
| MAXX              | Finds the max value after applying row-wise calculation | <code>MAXX(Sales, Sales[Profit])</code> (Max Profit)                               |
| MINX              | Finds the min value after applying row-wise calculation | <code>MINX(Sales, Sales[Cost])</code> (Min Cost)                                   |
| COUNTX            | Counts the number of rows meeting a condition           | <code>COUNTX(Sales, Sales[Quantity] &gt; 2)</code> (Orders with more than 2 items) |
| FILTER            | Filters rows based on a condition                       | <code>FILTER(Sales, Sales[Profit] &gt; 100)</code> (High-Profit Orders)            |

# DAX Iterators (Aggregation functions X)

Perform calculations across a column or table, returning a single aggregated value.

## Example: Why Use an Iterator?

Let's say we have a Sales Table with Price and Quantity columns:

Question: How do we calculate Total Sales Revenue (Price \* Quantity)?

| Product  | Price (\$) | Quantity |
|----------|------------|----------|
| Laptop   | 1,000      | 2        |
| Mouse    | 30         | 5        |
| Keyboard | 50         | 3        |

## ✗ Using Standard Aggregation (Incorrect Approach)

Total Sales = SUM(Sales[Price]) \* SUM(Sales[Quantity])

- Problem: This formula multiplies column totals instead of row-level values.
- Incorrect Calculation:
  - SUM(Price) = 1,000 + 30 + 50 = 1,080
  - SUM(Quantity) = 2 + 5 + 3 = 10
  - 1,080 \* 10 = 10,800 (Incorrect!)

# DAX Iterators (Aggregation functions X)

Perform calculations across a column or table, returning a single aggregated value.

## Example: Why Use an Iterator?

Let's say we have a Sales Table with Price and Quantity columns:

Question: How do we calculate Total Sales Revenue (Price \* Quantity)?

| Product  | Price (\$) | Quantity |
|----------|------------|----------|
| Laptop   | 1,000      | 2        |
| Mouse    | 30         | 5        |
| Keyboard | 50         | 3        |

## ✔ Using an Iterator Function (Correct Approach)

Total Sales = **SUMX**(Sales, Sales[Price] \* Sales[Quantity])

- SUMX iterates row by row:
  - Laptop:  $1,000 \times 2 = 2,000$
  - Mouse:  $30 \times 5 = 150$
  - Keyboard:  $50 \times 3 = 150$
- Correct Total:  $2,000 + 150 + 150 = 2,300$

# Filtered Iterators: Using SUMX with FILTER

*Perform calculations across a column or table, returning a single aggregated value.*

## Scenario:

A retail company wants to sum the sales only for high-value products (Price > 500).

## Incorrect Approach (SUM on the Whole Table)

High Value Sales = SUM(Sales[Revenue])

## Correct Approach Using SUMX + FILTER

High Value Sales = **SUMX**(FILTER(Sales, Sales[Price] > 500), Sales[Price] \* Sales[Quantity])

## Explanation:

- FILTER(Sales, Sales[Price] > 500): Selects only rows where Price > 500.
- SUMX(..., Sales[Price] \* Sales[Quantity]): Calculates revenue only for those rows.

# Counting functions.

Count rows or specific values in a column.

## Key functions

**COUNT**: Counts non-blank rows in a column.

Example: *TotalTransactions* = **COUNT**(Sales[TransactionID])

**COUNTA**: Counts non-blank rows, including text and logical values.

Example: *TotalCustomers* = **COUNTA**(Customers[CustomerName])

**COUNTBLANK**: Counts blank values in a column.

Example: *MissingData* = **COUNTBLANK**(Sales[Revenue])

**DISTINCTCOUNT**: Counts unique values in a column.

Example: *UniqueCustomers* = **DISTINCTCOUNT**(Sales[CustomerID])

# Statistical functions.

Perform statistical analysis on data columns..

## Key functions

**MEDIAN**: Returns the median value in a column.

Example: *MedianSales* = **MEDIAN**(Sales[Revenue])

**STDEV.P**: Calculates the standard deviation of an entire population.

Example: *RevenueStDev* = **STDEV.P**(Sales[Revenue])

**STDEV.S**: Calculates the standard deviation of a sample.

Example: *SampleStDev* = **STDEV.S**(Sales[Revenue])

**PRODUCT**: Multiplies all values in a column.

Example: *TotalProduct* = **PRODUCT**(Sales[GrowthFactor])

# Logical functions.

Logical functions in DAX are used to evaluate conditions and return values based on the results of those evaluations.

## Key functions

**IF**: Performs conditional logic and returns one value if a condition is true and another if false..

Example: *HighSales* = **IF**(Sales[Revenue] > 5000, "High", "Low")

**IFERROR**: Returns a value if an expression results in an error.

Example: *SafeDivision* = **IFERROR**(Sales[Revenue] / Sales[Quantity], 0)

**AND / OR**: Combine multiple conditions.

Example: *HighProfit* = **IF**(**AND**(Sales[Revenue] > 5000, Sales[Profit] > 2000), "Yes", "No")

**SWITCH**: Evaluates an expression against multiple conditions and returns a value.

Example: *SalesCategory* = **SWITCH**(TRUE(), Sales[Revenue] > 10000, "Platinum",  
Sales[Revenue] > 5000, "Gold", "Silver")

# What is the SWITCH Function?

The **SWITCH** function evaluates an expression and returns a result based on matching predefined values. It is used to simplify multiple IF statements and improve readability & performance.

```
SWITCH(Expression,  
        Value1, Result1,  
        Value2, Result2,  
        Value3, Result3,  
        ...,  
        DefaultResult)
```

## 2 Example: Categorizing Sales Performance

### ✗ Using Nested IF Statements (Difficult to Read)

DAX

Copy Edit

```
Sales Category =  
IF(Sales[Total Revenue] > 50000, "High",  
   IF(Sales[Total Revenue] > 20000, "Medium",  
      "Low"))
```

- **Problem:** Hard to read & maintain when conditions increase.

### ✓ Using SWITCH (Cleaner & More Efficient)

DAX

Copy Edit

```
Sales Category =  
SWITCH(TRUE(),  
        Sales[Total Revenue] > 50000, "High",  
        Sales[Total Revenue] > 20000, "Medium",  
        "Low"  
)
```

# What is the SWITCH Function?

## 3 Example: Mapping Product Categories

📌 **Scenario:** A company wants to classify products into **categories** based on their Product ID.

### Using SWITCH to Assign Product Categories

DAX

📄 Copy ✎ Edit

```
Product Category =  
SWITCH(Sales[Product ID],  
    101, "Laptops",  
    102, "Monitors",  
    103, "Keyboards",  
    104, "Mice",  
    "Other"  
)
```

📌 **Explanation:**

- ✅ If Product ID = 101, it returns "Laptops".
- ✅ If Product ID = 102, it returns "Monitors".
- ✅ If no match is found, it returns "Other".

## **Why Use IF/SWITCH in DAX When We Can Use Conditional Columns in Power Query?**

# Power Query vs. DAX: The Key Differences

| Feature            | Power Query (M Language)                                                        | DAX (Report View)                                                        |
|--------------------|---------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| Where it runs      | Runs at the <b>data transformation level</b> (before loading to the model).     | Runs at the <b>visualization level</b> (after data is loaded).           |
| When it updates    | Applied <b>once during data refresh</b> .                                       | Updates <b>dynamically based on user interaction</b> (slicers, filters). |
| Performance Impact | Reduces model size (pre-computed before loading).                               | Calculated on-the-fly, which can slow performance on large datasets.     |
| Context Awareness  | Cannot respond to slicers or dynamic filters.                                   | Can dynamically adjust values based on filters & visuals.                |
| Best Used For      | <b>Static classifications</b> (e.g., "New Customer" or "High Revenue Product"). | <b>Dynamic calculations</b> (e.g., "Total Sales for Selected Month").    |

# Power Query vs. DAX: The Key Differences

## 2 When to Use Power Query for IF-ELSE Logic?

- ✓ For static calculations that don't change with filters.
- ✓ For pre-processed classifications (e.g., category assignments).
- ✓ To reduce memory usage & improve performance.

### 📌 Example (Power Query Conditional Column):

- If we want to classify customers based on **total purchases**, we can add a **calculated column** in Power Query:

Power

📄 Copy ✎ Edit

```
if [Total Purchases] > 5000 then "VIP"
else if [Total Purchases] > 1000 then "Regular"
else "New Customer"
```

- **Best for:**
  - Customer segmentation
  - Product categories
  - Fixed discount tiers

# Power Query vs. DAX: The Key Differences

## 3 When to Use DAX IF/SWITCH in Report View?

- ✓ For calculations that depend on user selections (filters, slicers, or visuals).
- ✓ When you need dynamic calculations that change in real time.
- ✓ When relationships between tables require on-the-fly adjustments.

### 📌 Example (DAX in Report View - Dynamic Calculation):

- Suppose we want to **classify customers dynamically based on their purchases in the selected period** (e.g., the last 6 months):

DAX

📄 Copy 🖋 Edit

```
Customer Status =  
SWITCH(  
    TRUE(),  
    SUM(Sales[Total Purchases]) > 5000, "VIP",  
    SUM(Sales[Total Purchases]) > 1000, "Regular",  
    "New Customer"  
)
```

- **Best for:**
  - Dynamic ranking of customers based on **selected timeframe**
  - Conditional formatting in Power BI based on filter selection

# **Text Functions.**

*A Beginner's Guide to Writing DAX Formulas.*

# Text functions.

Powerful Tools for Text Manipulation.

## Key functions

**CONCATENATE**: Combines two text strings into one.

Example: *FullName* = **CONCATENATE**(*Employees[FirstName]*, " " & *Employees[LastName]*)

**COMBINEVALUES**: Combines multiple text strings with a delimiter..

Example: *FullName* = **COMBINEVALUES**(" ", *Employees[FirstName]*, *Employees[LastName]*)

**FORMAT**: Converts a value to a specific format.

Example: *FormattedDate* = **FORMAT**(*Orders[OrderDate]*, "DD-MM-YYYY")

**LEFT, MID, RIGHT**: Extract parts of a string.

Example: *First3Chars* = **LEFT**(*Products[ProductCode]*, 3)

*MiddlePart* = **MID**(*Products[ProductCode]*, 4, 5)

*Last2Chars* = **RIGHT**(*Products[ProductCode]*, 2).

# Text functions.

Powerful Tools for Text Manipulation.

## Key functions

**SEARCH/FIND**: Locate a substring within a text string.

Example: *Position* = **SEARCH**("-", Products[SKU], 1)

**REPLACE**: Replace part of a string with new text based on position.

Example: *ReplacePart* = **REPLACE**("ABC123", 1, 3, "XYZ")

**SUBSTITUTE**: Replace occurrences of specific text.

Example: *ReplaceDash* = **SUBSTITUTE**("123-456-789", "-", "/")

**TRIM**: Removes extra spaces from text.

Example: *CleanedText* = **TRIM**(Customers[Name]).

# **Date & Time Functions.**

*A Beginner's Guide to Writing DAX Formulas.*

# Date & Time Functions in DAX.

*Powerful Tools for Time-Based Analysis.*

Date & Time functions in DAX allow you to manipulate, analyze, and perform calculations on date and time data.

**YEAR / MONTH / DAY**: Extract components of a date..

*Example: Year = YEAR(Orders[OrderDate])*

**WEEKDAY**: Returns the day of the week as a number.

*Example: DayOfWeek = WEEKDAY(Orders[OrderDate], 2) -- 2: Monday as the first day*

**FORMAT**: Converts a date to a formatted string.

*Example: FormattedDate = FORMAT(Orders[OrderDate], "DD-MM-YYYY")*

**TODAY**: Returns the current date.

*Example: DaysSinceOrder = TODAY() - Orders[OrderDate]*

# Date & Time Functions in DAX.

*Powerful Tools for Time-Based Analysis.*

Date & Time functions in DAX allow you to manipulate, analyze, and perform calculations on date and time data.

**EDATE / EOMONTH:** Adds/subtracts months to/from a date.

*Example:  $NextMonth = EDATE(Orders[OrderDate], 1)$*

*$MonthEnd = EOMONTH(Orders[OrderDate], 0)$*

# Time Intelligence Functions.

*Powerful Tools for Time-Based Analysis.*

Date & Time functions in DAX allow you to manipulate, analyze, and perform calculations on date and time data.

**DATEDIFF**: Returns the difference between two dates.

*Example: DaysBetween = DATEDIFF(Orders[OrderDate], TODAY(), DAY)*

**CALENDAR / CALENDARAUTO**: Creates a table of dates.

*Example: CalendarTable = CALENDAR(DATE(2022, 1, 1), DATE(2022, 12, 31))*

# **Most Common Practices.**

*A Beginner's Guide to Writing DAX Formulas.*

# Practical Use Cases.

Powerful Tools for Time-Based Analysis.

## Aggregation Over Specific Periods

**TOTALYTD**: Calculates the year-to-date total for a measure.

Syntax: `TOTALYTD(<Expression>, <Dates>, [<Filter>], [<YearEndDate>])`

Example: `SalesYTD = TOTALYTD(SUM(Sales[Revenue]), Dates[Date])`

**TOTALQTD**: Calculates the quarter-to-date total for a measure.

Syntax: `TOTALQTD (<Expression>, <Dates>, [<Filter>], [<YearEndDate>])`

Example: `SalesQTD = TOTALQTD (SUM(Sales[Revenue]), Dates[Date])`

**TOTALMTD**: Calculates the month-to-date total for a measure.

Syntax: `TOTALMTD (<Expression>, <Dates>, [<Filter>], [<YearEndDate>])`

Example: `SalesYTD = TOTALMTD (SUM(Sales[Revenue]), Dates[Date])`

# Practical Use Cases.

*Powerful Tools for Time-Based Analysis.*

## Previous Period Calculations

**PREVIOUSYEAR**: Returns a table with the same period in the previous year.

*Syntax: PREVIOUSYEAR(<Dates>, [<YearEndDate>])*

*Example: SalesPreviousYear = CALCULATE(SUM(Sales[Revenue]), PREVIOUSYEAR(Dates[Date]))*

**PREVIOUSQUARTER**: Returns the same period in the previous quarter.

*Syntax: PREVIOUSQUARTER(<Dates>)*

**PREVIOUSMONTH**: Returns the same period in the previous month.

*Syntax: PREVIOUSMONTH(<Dates>)*

**PREVIOUSDAY**: Returns the same period in the previous day.

*Syntax: PREVIOUSDAY(<Dates>)*

# Practical Use Cases.

*Powerful Tools for Time-Based Analysis.*

## Next Period Calculations

**NEXTYEAR**: Returns the same period in the next year.

*Syntax: NEXTYEAR(<Dates>)*

**NEXTQUARTER**: Returns the same period in the next quarter.

*Syntax: NEXTQUARTER (<Dates>)*

**NEXTMONTH**: Returns the same period in the next month.

*Syntax: NEXTMONTH (<Dates>)*

# Practical Use Cases.

*Powerful Tools for Time-Based Analysis.*

## Rolling and Moving Averages

These functions calculate running totals or moving averages.

**DATESYTD (<Dates>, [<YearEndDate>])**: Returns the dates year-to-date, quarter-to-date, or month-to-date.

*Syntax: RollingYTD = CALCULATE(SUM(Sales[Revenue]), **DATESYTD**(Dates[Date]))*

**FIRSTDATE / LASTDATE**: Returns the first or last date in a table..

*Syntax: FIRSTDATE(<Dates>)*

*LASTDATE(<Dates>)*

# Relationship Functions.

*A Beginner's Guide to Writing DAX Formulas.*

# Relationship Function.

Managing Relationships for Data Analysis in Power BI.

## What Are Relationship Functions?

Relationship functions in DAX allow you to work with relationships between tables in your data model.

They help retrieve related values, manage filtering, and adjust relationship behaviors dynamically.

# Relationship Function.

Managing Relationships for Data Analysis in Power BI.

## Key functions:

**RELATED:** Returns a single value from a related table for the current row.

- *ProductName = **RELATED**(Products[ProductName])*

**RELATEDTABLE:** Returns a table of all rows related to the current row.

- *TotalSalesPerProduct = SUMX(RELATEDTABLE(Sales), Sales[Revenue])*

**USERELATIONSHIP:** Forces DAX to use an inactive relationship instead of the active one.

- *SalesByDeliveryDate = CALCULATE(SUM(Sales[Revenue]), **USERELATIONSHIP**(Sales[DeliveryDate], Dates[Date]))*

**CROSSFILTER:** Modifies the cross-filter direction of a relationship dynamically.

- *AdjustedSales = CALCULATE(SUM(Sales[Revenue]), **CROSSFILTER**(Products[ProductID], Sales[ProductID], Both))*

# Create Calendar table.

**Use M code in Power query editor: Tạo bảng trống → Advanced editor → Nhập M code**

**let**

*// Lấy ngày bắt đầu và ngày kết thúc từ bảng Fact Table*

*StartDate = List.Min(FactTable(Order\_Date)),*

*EndDate = List.Max(FactTable(Order\_Date)),*

*// Tạo danh sách ngày từ StartDate đến EndDate*

*DateList = List.Dates(StartDate, Duration.Days(EndDate - StartDate) + 1, #duration(1, 0, 0, 0)),*

*// Chuyển danh sách ngày thành bảng*

*DataTable = Table.FromList(DateList, Splitter.SplitByNothing(), {"Date"}),*

*// Chuyển đổi cột Date sang kiểu dữ liệu Date*

*DataTableWithColumns = Table.TransformColumnTypes(DataTable, {"Date", type date})*

**in**

*DataTableWithColumns*

# Create Calendar table.

## Tạo bảng calendar trên Front-end: Modeling > New Table.

*CalendarTable =*

*ADDCOLUMNS(*

*CALENDAR(*

*MIN(FactTable[Order\_Date]),*

*MAX(FactTable[Order\_Date])*

*),*

*"Year", YEAR([Date]),*

*"Month", FORMAT([Date], "MMMM"),*

*"MonthNumber", MONTH([Date]),*

*"Quarter", "Q" & FORMAT([Date], "Q"),*

*"Weekday", FORMAT([Date], "dddd"),*

*"WeekNumber", WEEKNUM([Date])*

*)*

# Filter Functions.

*A Beginner's Guide to Writing DAX Formulas.*

CALCULATE, FILTER, ALL, ALLEXCEPT, ALLSELECTED, ...

# Filter Functions.

*A Beginner's Guide to Writing DAX Formulas.*

CALCULATE, FILTER, ALL, ALLEXCEPT, ALLSELECTED, ...

**DAX FILTER functions** allow us to manipulate tables and control filter contexts in Power BI calculations. These functions help refine data before applying aggregations, giving more control over what data is included or excluded in calculations.

# CALCULATE Function.

The Most Powerful DAX Function

## What is CALCULATE?

The CALCULATE function evaluates an expression in a modified filter context, allowing you to change, add, or remove filters dynamically.

**Syntax:** **CALCULATE**(*<Expression>*, *<Filter1>*, *<Filter2>*, ...)

**Expression:** The aggregation or calculation you want to perform.

**Filter:** One or more conditions that modify the filter context.

## Example

### Basic Example: Applying a Filter:

- SalesEast = **CALCULATE**(SUM(Sales[Revenue]), Sales[Region] = "East" )

### Using Multiple Filters:

- HighValueSalesEast = **CALCULATE**(SUM(Sales[Revenue]), Sales[Region] = "East", Sales[Revenue] > 500)

### Using FILTER for Complex Logic:

- SalesAboveCost = **CALCULATE**(SUM(Sales[Revenue]), **FILTER**(Sales, Sales[Cost] > **RELATED**(Product[Target\_Cost])))

# FILTER Function.

Row-by-Row Table Filtering.

## What is FILTER?

The FILTER function returns a table containing rows that meet a specified condition.

It is evaluated row by row and often used inside functions like CALCULATE, SUMX, or COUNTROWS.

**Syntax:** **FILTER**(<Table>, <Condition>)

**Table:** The table to be filtered.

**Condition:** A logical expression that determines which rows to keep.

## Example

### Using FILTER Inside CALCULATE::

- SalesAbove1000 = **CALCULATE**(SUM(Sales[Revenue]), **FILTER**(Sales, Sales[Revenue] > 1000))

### Using Multiple Filters:

- HighValueSalesEast = **CALCULATE**(SUM(Sales[Revenue]), **Sales[Region] = "East", Sales[Revenue] > 500**)

### FILTER with ALL for Custom Totals:

- SalesIgnoreProduct = **CALCULATE**(SUM(Sales[Revenue]), **FILTER**(ALL(Sales[Product]), Sales[Region] = "East"))

# ALL Function.

Removes All Filters on a Table or Column.

## What is ALL?

- Ignores existing filters and returns all rows in a table or column.
- Used when we need global calculations (e.g., grand total comparisons)..

**Syntax:** `ALL(<Table or Column>)`

**Table:** The table to be not filtered.

## Example

### Using ALL Inside CALCULATE:

- *Total Sales (No Filters)* = `CALCULATE( SUM( Sales[Amount] ), ALL(Sales))`
- *% of Total Sales* = `DIVIDE( SUM(Sales[Amount]), CALCULATE( SUM( Sales[Amount] ), ALL(Sales)))`
  - *ALL(Sales)* removes any active filters (e.g., product, region, date).
  - The measure always returns total sales across all filters.
  - Useful for % of Total Sales per category.

# ALLEXCEPT Function.

Removes All Filters Except Specific Columns.

## What is ALLEXCEPT?

- Removes all filters except the ones specified.
- Useful when keeping a specific filter while ignoring others.

**Syntax:** `ALLEXCEPT(<Table, Column1, Column2, ...>)`

**Table:** columns will be not filtered.

## Example:

### Total Sales by Year (Ignoring Region):

- *Total Sales by Year = CALCULATE( SUM(Sales[Amount] ), ALLEXCEPT( Sales, Sales[Year] ) )*
  - All filters (e.g., Region, Product) are removed.
  - Only Year remains as a filter.
  - Useful for yearly comparisons while ignoring other filters.

# REMOVEFILTERS Function.

Clears Filters from a Column/Table While Keeping Others.

## What is REMOVEFILTERS?

- Similar to ALL(), but more selective.
- Clears filters only from specific columns.

**Syntax:** **REMOVEFILTERS**(<Table, Column1, Column2, ...>)

**Table:** columns will be not filtered.

## Example:

### Sales Ignoring Product Filters:

- *Total Sales (Ignore Product) = CALCULATE( SUM(Sales[Amount]), **REMOVEFILTERS**( Sales[Product]) )*
  - *If the user filters by Product, this measure ignores that filter.*
  - *Region, Date, and other filters still apply.*
  - *Used in multi-filter reports where certain filters need to be ignored.*

# SELECTEDVALUE Function.

Returns the User's Selection from a Slicer.

## What is SELECTEDVALUE?

- Returns the selected value from a column (or a default value if multiple are selected).
- Used in dynamic report titles & calculations.

**Syntax:** **REMOVEFILTERS**(<Table, Column1, Column2, ...>)

**Table:** columns will be not filtered.

## Example:

### Dynamic Title Based on Selected Year:

- *Report Title = "Sales Report for " & SELECTEDVALUE(Sales[Year], "All Years")*
  - *If 2023 is selected in a slicer, the title updates to "Sales Report for 2023".*
  - *If no selection is made, it defaults to "Sales Report for All Years".*
